Chapter 1

Compatibility

1.1 System interfaces compatible with the Single Unix Specification, Version 4:

Note that the core of the Single Unix Specification, Version 4 is also IEEE Std 1003.1-2008 (POSIX.1-2008).

1.7 Implementation Notes

chroot only emulates a chroot function call by keeping track of the current root and accomodating this in the file related function calls. A real chroot functionality is not supported by Windows however.

`clock_nanosleep` currently supports only `CLOCK_REALTIME` and `CLOCK_MONOTONIC`. `clock_setres`, `clock_gettime`, and `timer_create` currently support only `CLOCK_REALTIME`.

POSIX file locks via `fcntl` or `lockf`, as well as BSD `flock` locks are advisory locks. They don't interact with Windows mandatory locks, nor do POSIX `fcntl` locks interfere with BSD `flock` locks or vice versa.

BSD file locks created via `flock` are only propagated to the direct parent process, not to grand parents or sibling processes. The locks are only valid in the creating process, its parent process, and subsequently started child processes sharing the same file descriptor.

In very rare circumstances an application would want to use Windows mandatory locks to interact with non-Cygwin Windows processes accessing the same file (databases, etc). For these purposes, the entire locking mechanism (`fcntl/flock/lockf`) can be switched to Windows mandatory locks on a per-descriptor/per-process basis. For this purpose, use the call

```
fcntl (fd, F_LCK_MANDATORY, 1);
```

After that, all file locks on this descriptor will follow Windows mandatory record locking semantics: Locks are per-descriptor/per-process; locks are not propagated to child processes, not even via `execve`; no atomic replacement of read locks with write locks and vice versa on the same descriptor; locks have to be unlocked exactly as they have been locked.

`fpclassify`, `isfinite`, `isgreater`, `isgreaterequal`, `isinf`, `isless`, `islessequal`, `islessgreater`, `isnan`, `isnormal`, `isunordered`, and `signbit` only support float and double arguments, not long double arguments.

`getitimer` and `setitimer` only support `ITIMER_REAL` for now.

`link` will fail on FAT, FAT32, and other filesystems not supporting hardlinks, just as on Linux.

`lseek` only works properly on files opened in binary mode. On files opened in textmode (via mount mode or explicit open flag) its positioning is potentially unreliable.

`setuid` is only safe against reverting the user switch after a call to one of the `exec(2)` functions took place. Windows doesn't support a non-revertable user switch within the context of Win32 processes.

`vfork` just calls `fork`.

`vhangup` and `revoke` always return -1 and set `errno` to `ENOSYS`. `grantpt` and `unlockpt` always just return 0.

The XSI IPC functions `semctl`, `semget`, `semop`, `shmat`, `shmctl`, `shmdt`, `shmget`, `msgctl`, `msgget`, `msgrcv` and `msgsnd` are only available when `cygserver` is running.

The Linux-specific function `quotactl` only implements what works on Windows: Windows only supports user block quotas on NTFS, no group quotas, no inode quotas, no time constraints.

`qsort_r` is available in both BSD and GNU flavors, depending on whether `_BSD_SOURCE` or `_GNU_SOURCE` is defined when compiling.

Chapter 2

Cygwin Functions

2.1 Path conversion functions

These functions are specific to Cygwin itself, and probably won't be found anywhere else.

2.1.1 cygwin_conv_path

```
extern "C" ssize_t cygwin_conv_path(cygwin_conv_path_t what, const void * from, void * to, size_t size);
```

Use this function to convert POSIX paths in *from* to Win32 paths in *to* or, vice versa, Win32 paths in *from* to POSIX paths in *to*. *what* defines the direction of this conversion and can be any of the below values.

CCP_POSIX_TO_WIN_A	/* from is char *posix, to is char *win32 */
CCP_POSIX_TO_WIN_W	/* from is char *posix, to is wchar_t *win32 */
CCP_WIN_A_TO_POSIX	/* from is char *win32, to is char *posix */
CCP_WIN_W_TO_POSIX	/* from is wchar_t *win32, to is char *posix */

You can additionally or the following values to *what*, to define whether you want the resulting path in *to* to be absolute or if you want to keep relative paths in relative notation. Creating absolute paths is the default.

CCP_ABSOLUTE = 0,	/* Request absolute path (default). */
CCP_RELATIVE = 0x100	/* Request to keep path relative. */

size is the size of the buffer pointed to by *to* in bytes. If *size* is 0, `cygwin_conv_path` just returns the required buffer size in bytes. Otherwise, it returns 0 on success, or -1 on error and `errno` is set to one of the below values.

EINVAL	what has an invalid value or from is NULL.
EFAULT	from or to point into nirvana.
ENAMETOOLONG	the resulting path is longer than 32K, or, in case of what == CCP_POSIX_TO_WIN_A, longer than MAX_PATH.
ENOSPC	size is less than required for the conversion.

Example 2.1 Example use of cygwin_conv_path

```
#include <sys/cygwin.h>

/* Conversion from incoming Win32 path given as wchar_t *win32 to POSIX path.
   If incoming path is a relative path, stick to it. First ask how big
   the output buffer has to be and allocate space dynamically. */
ssize_t size;
char *posix;
```

```

size = cygwin_conv_path (CCP_WIN_W_TO_POSIX | CCP_RELATIVE, win32, NULL, 0);
if (size < 0)
    perror ("cygwin_conv_path");
else
{
    posix = (char *) malloc (size);
    if (cygwin_conv_path (CCP_WIN_W_TO_POSIX | CCP_RELATIVE, win32,
                          posix, size))
        perror ("cygwin_conv_path");
}

```

2.1.2 cygwin_conv_path_list

extern "C" ssize_t **cygwin_conv_path_list**(cygwin_conv_path_t what, const void * from, void * to, size_t size);

This is the same as `cygwin_conv_path`, but the input is treated as a path list in \$PATH or %PATH% notation.

If *what* is CCP_POSIX_TO_WIN_A or CCP_POSIX_TO_WIN_W, given a POSIX \$PATH-style string (i.e. /foo:/bar) convert it to the equivalent Win32 %PATH%-style string (i.e. d:\;e:\bar).

If *what* is CCP_WIN_A_TO_POSIX or CCP_WIN_W_TO_POSIX, given a Win32 %PATH%-style string (i.e. d:\;e:\bar) convert it to the equivalent POSIX \$PATH-style string (i.e. /foo:/bar).

size is the size of the buffer pointed to by *to* in bytes.

See also [cygwin_conv_path](#)

2.1.3 cygwin_create_path

extern "C" void * **cygwin_create_path**(cygwin_conv_path_t what, const void * from);

This is equivalent to the `cygwin_conv_path`, except that `cygwin_create_path` does not take a buffer pointer for the result of the conversion as input. Rather it allocates the buffer itself using `malloc(3)` and returns a pointer to this buffer. In case of error it returns NULL and sets `errno` to one of the values defined for `cygwin_conv_path`. Additionally `errno` can be set to the below value.

ENOMEM	Insufficient memory was available.
--------	------------------------------------

When you don't need the returned buffer anymore, use `free(3)` to deallocate it.

See also [cygwin_conv_path](#)

2.1.4 cygwin_posix_path_list_p

extern "C" int **cygwin_posix_path_list_p**(const char *path);

This function tells you if the supplied *path* is a POSIX-style path (i.e. posix names, forward slashes, colon delimiters) or a Win32-style path (drive letters, reverse slashes, semicolon delimiters). The return value is true if the path is a POSIX path. Note that "_p" means "predicate", a lisp term meaning that the function tells you something about the parameter.

2.1.5 cygwin_split_path

extern "C" void **cygwin_split_path** (const char * path, char * dir, char * file);

Split a path into the directory and the file portions. Both *dir* and *file* are expected to point to buffers of sufficient size.

Example 2.2 Example use of `cygwin_split_path`

```
char dir[200], file[100];
cygwin_split_path("c:/foo/bar.c", dir, file);
printf("dir=%s, file=%s\n", dir, file);
```

2.2 Helper functions to change user context

2.2.1 `cygwin_logon_user`

extern "C" HANDLE **cygwin_logon_user**(const struct passwd *passwd_entry, const char *password);

Given a pointer to a passwd entry of a user and a cleartext password, returns a HANDLE to an impersonation token for this user which can be used in a subsequent call to `cygwin_set_impersonation_token` to impersonate that user. This function can only be called from a process which has the required NT user rights to perform a logon.

See also the chapter [Switching the user context](#) in the Cygwin User's guide.

See also [cygwin_set_impersonation_token](#)

2.2.2 `cygwin_set_impersonation_token`

extern "C" void **cygwin_set_impersonation_token**(const HANDLE token);

Use this function to enable the token given as parameter as impersonation token for the next call to `setuid` or `seteuid`. Use `cygwin_set_impersonation_token` together with `cygwin_logon_user` to impersonate users using password authentication.

See also the chapter [Switching the user context](#) in the Cygwin User's guide.

See also [cygwin_logon_user](#)

2.3 Miscellaneous functions

2.3.1 `cygwin_attach_handle_to_fd`

extern "C" int **cygwin_attach_handle_to_fd**(char *name, int fd, HANDLE handle, int bin, int access);

This function can be used to turn a Win32 "handle" into a posix-style file handle. `fd` may be -1 to make cygwin allocate a handle; the actual handle is returned in all cases.

Even after using function, Cygwin doesn't know anything about the underlying file or device. It just tries to supply the typical file functions on a "best-effort" basis. Use with care. Don't expect too much.

2.3.2 `cygwin_internal`

extern "C" DWORD **cygwin_internal**(cygwin_getinfo_types t, ...);

This function gives you access to various internal data and functions. It takes two arguments. The first argument is a type from the 'cygwin_getinfo_types' enum. The second is an optional pointer.

Stay away unless you know what you're doing.

2.3.3 `cygwin_stackdump`

extern "C" void **cygwin_stackdump**(void);

Outputs a stackdump to stderr from the called location.
